## tutorial

Bob Kanefsky

# What is Clash?

- ▶ “C & Lisp Abstract Syntax Harmony”
- ▶ A way to compile both C and Lisp data structures from the same source files.
- ▶ A language for declaring message names
- ▶ A C code generator that hides boilerplate details
  - » freeing data allocated by another function
  - » “unmarshalling” bytes into structures
  - » type casting
- ▶ Written for DS1, implemented in Lisp.
- ▶ Called from command line or loaded into Lisp.

# Related topics to cover

- ▶ Marshalling
- ▶ Uses of Clash
  - » Compiling flight software's IPC code (C and Lisp)
  - » Compiling flight software's telemetry code (Lisp only)
  - » Converting scripts to ground commands
  - » Generating message-related test tools

# Definition of terms

## IPC

Inter-Process Communications package  
by Reid Simmons  
used by C and Lisp FSW

## marshal

to place bytes from a data structure in a standard order for transmission

## unmarshal

to place bytes from an incoming stream into a data structure in a machine dependent,  
compiler-dependent order

## Clash Preprocessor

Used for each C and Lisp module, to turn .clash files into .h files for C  
Optionally used by C modules to generate wrappers to hide IPC-specific code

## Clash Library for Lisp

A Lisp module, used mostly at compiletime for reading .clash and .h files.

## clomp

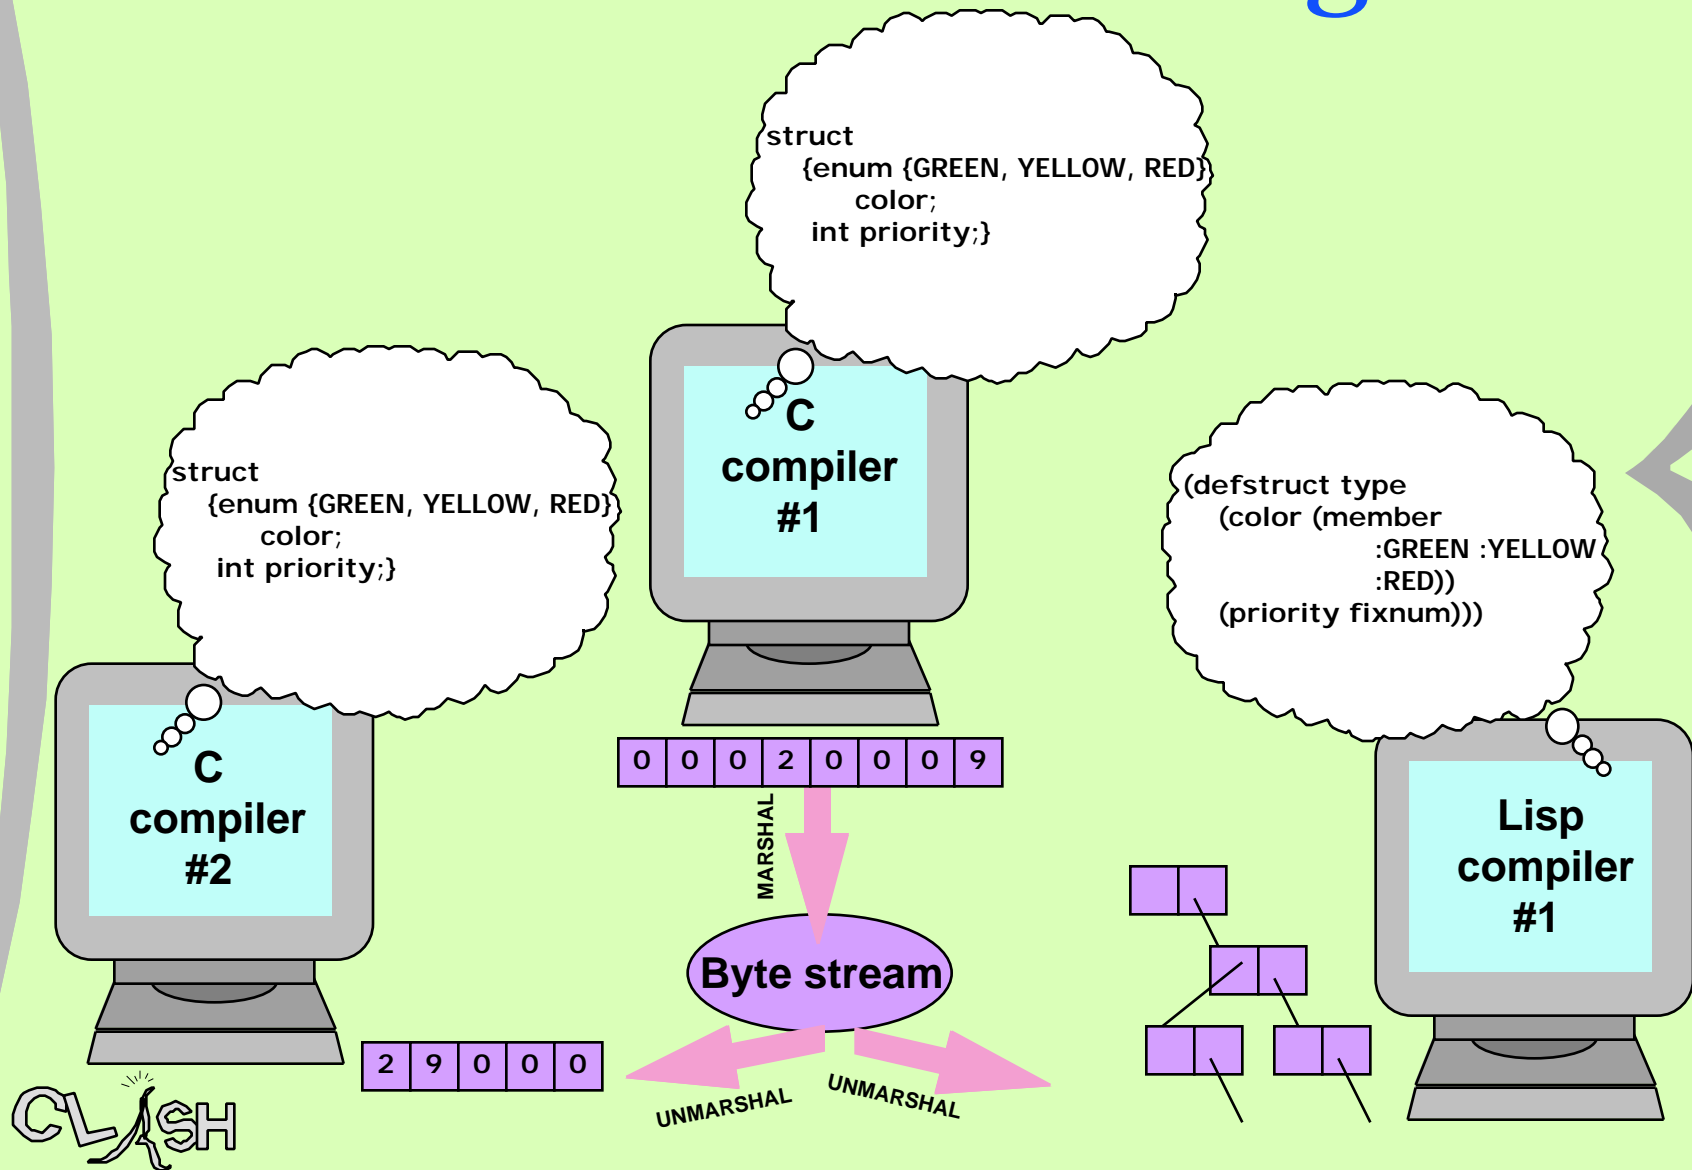

Any Clash-output Messaging Program (usually in C)

# Independencies

- ▶ Marshalling can be used for more than IPC
- ▶ Clash can be used for more than marshalling and IPC

# What is “marshalling”?

# Clash takes care of the parallel definitions

**.clash**

*source code  
written by user*

```
(defargtype foo ()  
  (structure  
    (color (enumerated (GREEN yellow red)))  
    (priority (integer :min 0 :max 1000000))))
```

*generates:*

```
typedef struct  
{enum {GREEN, YELLOW, RED}  
  color;  
  int priority;} foo
```

**.h**

```
(defstruct foo  
  (color (member  
    :GREEN :YELLOW  
    :RED))  
  (priority fixnum)))
```

**Lisp**

```
{{enum GREEN,YELLOW,RED},int}
```

**format string**

- » Clash preprocessor converts .clash to .h
- » Clash library for Lisp can read either .clash or .h directly at compiletime.

# Sample use of Clash

```
(defargtype size_name (enumerated (LITTLE GIANT)))  
(defargtype color_name (enumerated (RED YELLOW GREEN BLUE PURPLE)))  
(defargtype identification_type (enumerated (ROCKS MEN WOMEN CVENTIPEDES)))  
(defmessage PICTURE_CONTENTS_IDENTIFIED ((count (integer :maximum 1000)  
                                           (size size_name) (color color_name)  
                                           (type identification_type)))
```

```
CLASH_declare_publishers (IMAGE_RECOGNIZER)  
    PICTURE_CONTENTS_IDENTIFIED  
    PICTURE_ERROR)  
CLASH_declare_handlers (SMART_EXECUTIVE)  
    PICTURE_CONTENTS_IDENTIFIED
```

Then write normal C or Lisp functions:

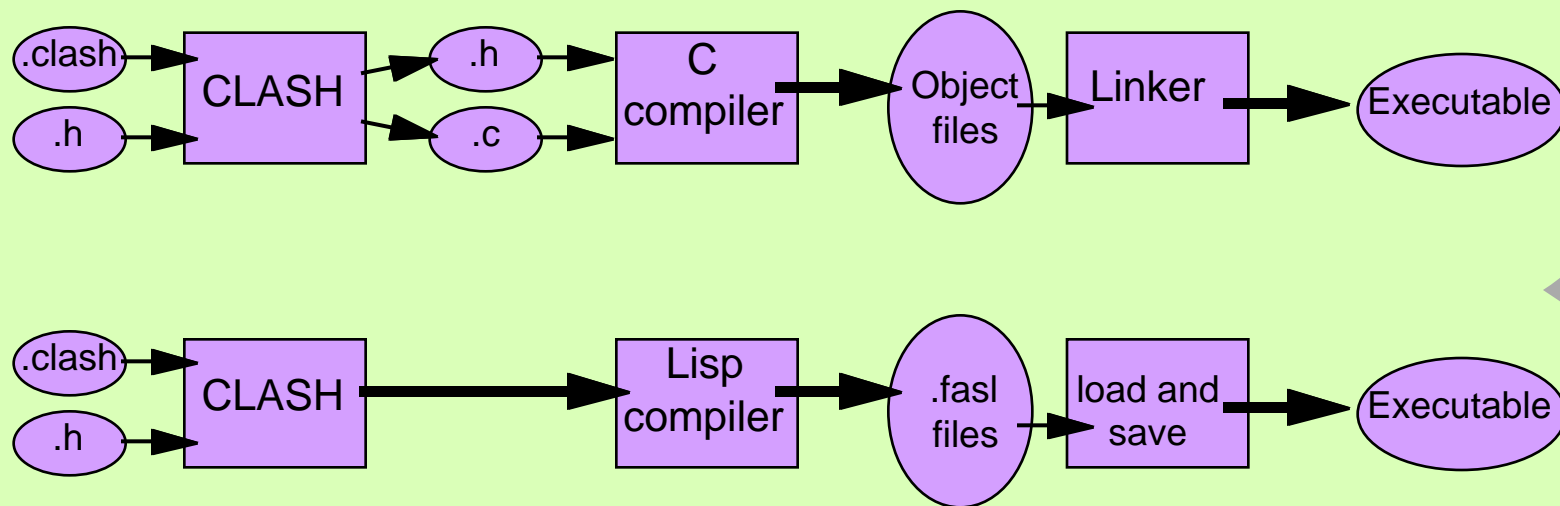

```
extern IMAGE_RECOGNIZER_send_PICTURE_CONTENTS_IDENTIFIED  
    (short count, size_name size, color_name color, identification_type type);  
IMAGE_RECOGNIZER_send_PICTURE_CONTENTS_IDENTIFIED (3, LITTLE, GREEN, MEN);
```

```
(defun SMART_EXECUTIVE_handle_PICTURE_CONTENTS_IDENTIFIED (count size color type)  
  (when (dangerous-monster-p size color type) (run-like-heck))  
  (unless (equal type :ROCK) (set-beacon-mode *tone-for-interesting*)))
```

# Clash is a C preprocessor & Lisp macro package

# Clash is a functional layer on top of IPC library calls

# Clash for telemetry definitions

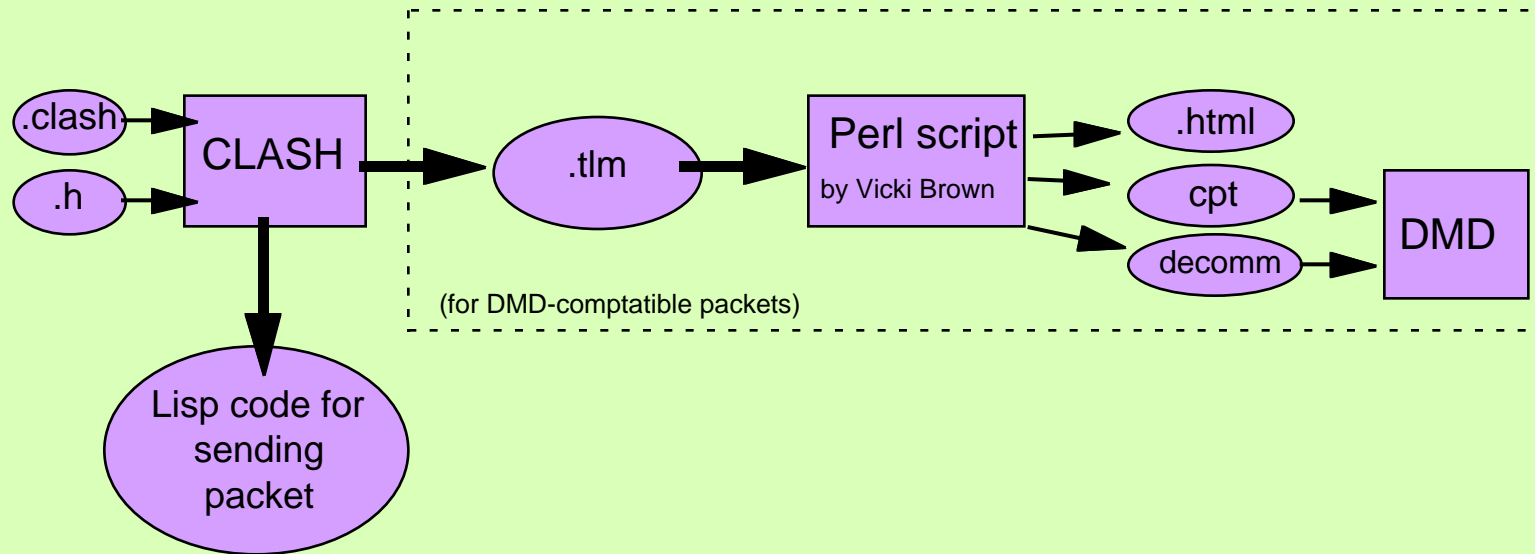

- ▶ Abstraction makes it easy to take a definition intended for use with IPC and re-use it for another type of communication.
  - » Here's the entire programming task for a Lisp programmer who wants to send a telemetry packet that corresponds to an existing IPC message:

**defmessage-with-telemetry**

**defpublisher-with-telemetry**

# Lisp telemetry interface

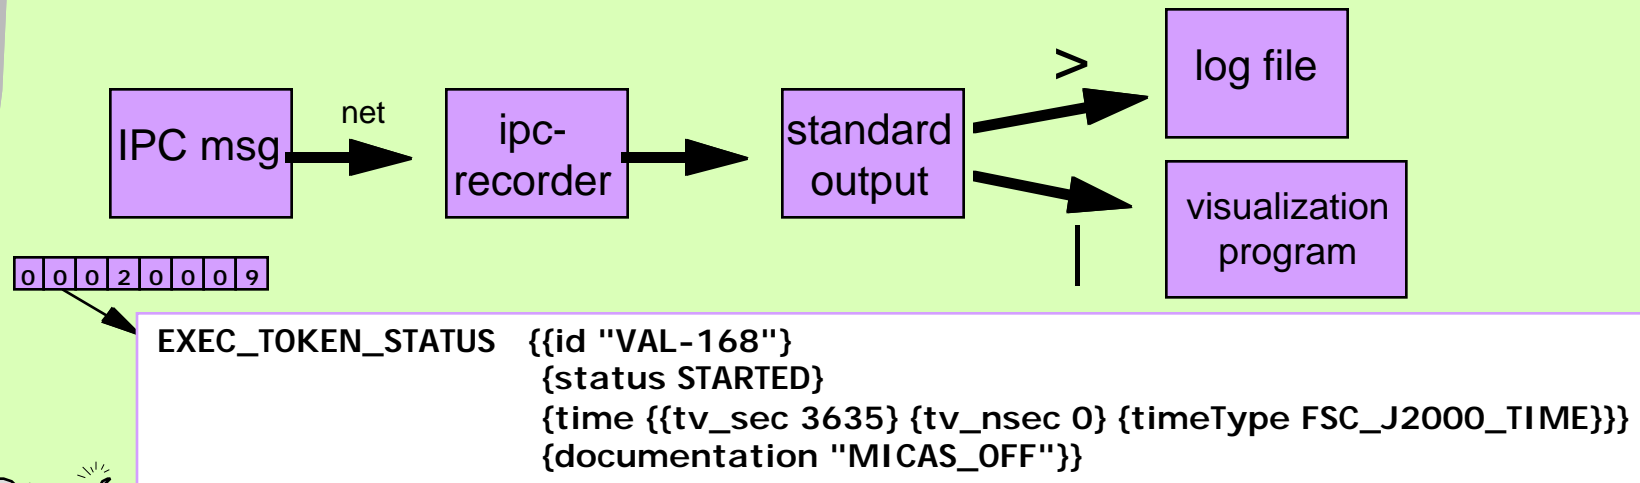

# About clomps

- Given the message definitions, Clash can generate a clomp for printing all messages when received, replaying messages from a log file, or anything else that follows from the message definitions.

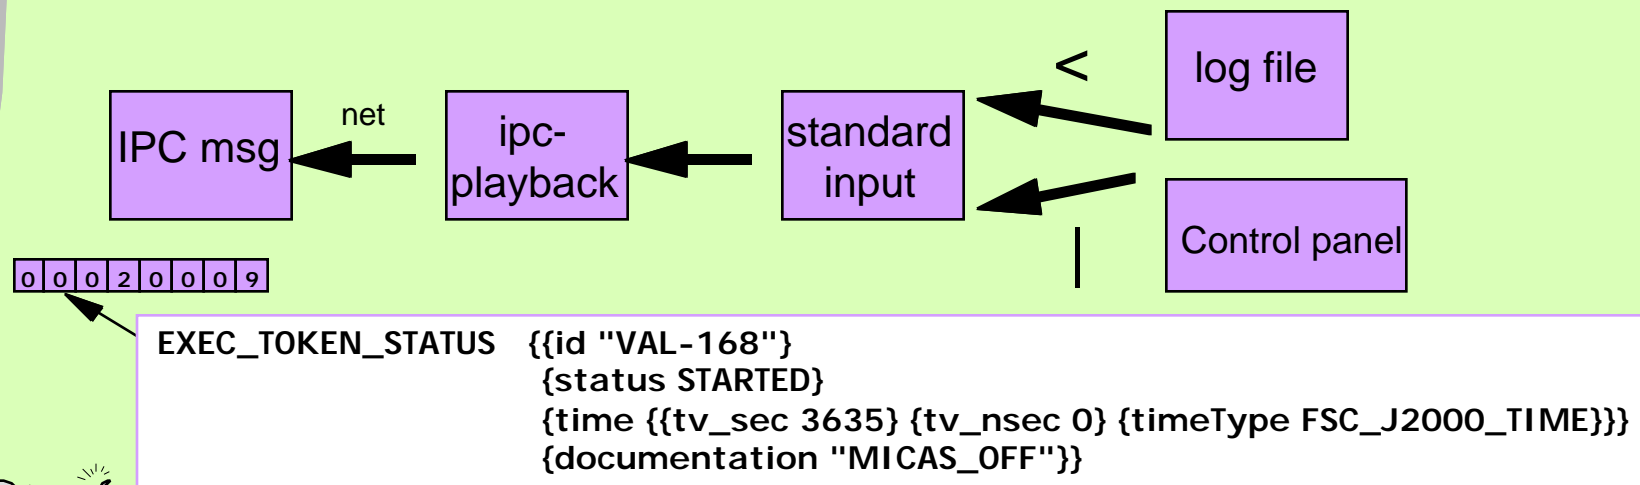

# ipc-recorder clomp

- ▶ Receives IPC messages
- ▶ Outputs a printed representation to standard output
- ▶ Applications
  - » Save a log file
  - » IPC front-end for non-IPC-aware visualization programs

# ipc-playback clomp

- ▶ Inputs a printed representation from standard input
- ▶ Sends IPC messages
- ▶ Applications
  - » Regression testing (also waits for selected messages)
  - » IPC front-end for non-IPC-aware control panels

# write-script-to-binary-files

## clomp

- ▶ A proposed interface for sending ground commands
- ▶ Input: same format as ipc-recorder produces
- ▶ Create input by any method:
  - » sending ipc-messages
  - » GUI for composing messages (hand-written or future clomp)
  - » text editor
- ▶ Output: for each message, a binary file with marshalled message contents
- ▶ Data flow: just like ipc-playback, but writes files instead of sending IPC messages.
